## Additive Algebra and new definition of what a Radical is

Be:

$$
\begin{equation*}
A^{n}=\sum_{1}^{A}\left(X^{n}-(X-1)^{n}\right) \tag{1}
\end{equation*}
$$

A Sum that can rise till any integer Upper Limit A, where $A^{n}$ is its result so its n -th Power.

Calling $M_{n}$ the Complicate Modulus: $M_{n}=\left(X^{n}-(X-1)^{n}\right)$ the Summand is capable to rise any n-th Power of an Integer, follows from the Telescoping Sum property.

Put now $x=X / K$ with $K \in \mathbb{N}$ equal for example to $10^{m}$.
It is not hard to prove that:

$$
\begin{equation*}
Q^{n}=\sum_{1 / K}^{Q} M_{n, K} \tag{2}
\end{equation*}
$$

Where: $Q$ can be an Integer but, now, also a Rational, or an Algebraic Irrational, since the New Rational Complicate Modulus becames:

$$
\begin{equation*}
M_{n, K}=\binom{n}{1} \frac{x^{n-1}}{K}-\binom{n}{2} \frac{x^{n-2}}{K^{2}}+\binom{n}{3} \frac{x^{n-3}}{K^{3}}-\ldots+/-\frac{1}{K^{n}} \tag{3}
\end{equation*}
$$

Here is an example of how to perform a Rational Step Sum, starting from a classic Integer Sum:

## Integration via INTEGER and RATIONAL Derivate

| $\mathbf{X}$ | $\mathbf{M} \mathbf{2}$ | $\mathbf{M 2 , k}=\mathbf{1 / 2}$ | SUM |
| :---: | :---: | ---: | ---: |
| 1 | $2^{*} 1-1$ | 1 | 1 |
| 2 | $2^{*} 2-1$ | 3 | 4 |
| 3 | $2^{*} 3-1$ | 5 | 9 |

$$
x=\frac{X}{K}
$$

Here is an example of how to perform A Step Sum with Known Irrational Values, too:

Of course at the Limit for $K \rightarrow \infty$ this Step Sum, becomes an Integral from 0 to the Upper Limit UL, where now UL can be also an Irrational Number with no restrictions.

We can now solve Any n-th Polinomial Equation if we put any Root, one by one as Upper Limit of a Sum where instead of $X^{n}$ terms into the Polynomial, we put the relative Sum:

$$
\begin{equation*}
x_{x=R x}^{n}=\sum_{1 / K}^{x=R x} M_{n, K} \tag{4}
\end{equation*}
$$

where $R x$ is any integer, or an Algebraic Irrational, or the closest to an Irrational Root $R x$ Algebraic Number we can reach Step $1 / K$ with an assigned suitable $K$.

And of course, more in general, we can rise terms of the type: $a X^{n}$
In case we know there is an Imaginary Root (due to a positive constant), then we need to change all the signs to $M_{n, K}$ so use the Imaginary Complicate Modululs is equal to:

$$
\begin{equation*}
M_{n, K, i}=-M_{n, K} \tag{5}
\end{equation*}
$$

I will prover hereafter, that in this way we'll skip the 10th Hilbert problem and the problem of Galois Group solvability, finding a solution to any n-th degree Polinomial Equation.

## The General Solving Method for Polinomyal Equations, using CMA:

Giving for know Abel-Ruffini theorem, hereafter we will show that a General Solving Algo for finding roots of any h-th Degree Polinomyal Equations exist, but produce, in case of non Rationals and non Algebraic Irrationals Roots, an infinite loop.

It also shows that a Radical is a more general concept that the one someone assign now to the solution of the equations of the type $X^{n}=P$ with $P \in \mathbb{R}$.

Here a simple example on the most famous, known as unsolvable, 5th degree equation $X^{5}-$ $X+1=0$

We can write, with precision $K=10^{m}$ :

$$
\begin{equation*}
X^{5}-X=-1 \Longrightarrow \sum_{1 / K}^{R x *} M_{5, K, i}-M_{1, K, i}=-1 \tag{6}
\end{equation*}
$$

Where $R x *=p / K$ is the Rational go most closer to out true root $R x$, in function of the $K$ we choose.
Or, defining a new Specific Complicate Modulus, for this quintic equation (that define the Polynomial Root Extractor ), we can write the -exact- formula:

$$
\begin{equation*}
\lim _{K \rightarrow \infty} \sum_{1 / K}^{R x} M_{X^{5}-X, K, i}=-1 \tag{7}
\end{equation*}
$$

Where $R x$ is of course any Real Root (or zero) coming from the Integral.
We will have for so Two type of solutions:

- Integers and Rationals with a finite number of digits comes in the Computational total precision, so $R_{x *}=R x$,
- while the other will be an apporximation till the maximum precision we are able to raise with our computer, so with our maximum $K$, and $R_{x *}<R x$.

If this concept is quite easy to be understood, what follow will be little more complicate to be uderstood if onw has not yet read my Vol.1:
In case we are able to recognize the Rational or the Irrational Part of the Root produce the infinite tail of digits, we can put it /them into the Sum Index, of the Step Sum, so into $K$ an in this way we can solve the equation in a finite number of Step.

It is also clear that in case we are not able to recognize the Rational or the Irrational with the infinite tail of digits, we have to stop somwhere the computation of the digist, just knwoing that the presence of a Rest assure us there are more digits over so our Result $R X *$ represent the first $m$ digits of a truncated Root $R x$.
For more info about the Complicate Modulus pls read my Vol. 1 (link at the end of this paper).

In the quintic example, since the root is an Irrational, keeping $K=10^{m}=10^{4}$ we get back exactly 4 correct digits (pls note that each digit you get rising $m$ of 1 , will be an exact decimal, one, not an approximated one).
The solution obey to this proven rule, is, theoretically due to the Algebraic construction of the solution, is capable also to work till the limit for $K \rightarrow \infty$ with an infinite number of digit, so it is not an approximation, that is just a technical problem as the same happens when you've as result f.ex. $\sqrt{2}$ and you've to show the value of the numerical result so someone. So a new more general $\sqrt{ }$ sign can be forged.

Returning to our example, so to the Quintic: the Modulus we must use to find the Roots in the Recursive Difference from the known constant, here: -1 looking to have Rest $=0$ (or as close to zero as we can in case of Irrational Roots) is:

$$
\begin{equation*}
M_{x^{5}-x, K, i}=-5 * \frac{x^{4}}{K}+10 * \frac{x^{3}}{K^{2}}-10 * \frac{x^{2}}{K^{3}}+5 * \frac{x}{K^{4}}-\frac{2}{K^{5}} \tag{8}
\end{equation*}
$$

That differs from the 5th line of the Tartaglia's triangle $M_{5, K, i}$ (represent $X^{5}$ ), for the last term, just, since we have to add with the right sign $M_{1, K, i}($ represent $X$ ), that is the constant $\frac{1}{K}$ summed K times.
And still if the Number $R_{x} *$ represent the Closest Rational to an Irrational Solution comes from a long computation of very long Rational digit numbers, we can affirm that we can always find any $R_{x}$ Root, using what I hope is clear now is a more General Root (Algebraic) Extractor (GRE theorem).

So the point is: I've produced a new more general definition for a Radical Root, finding a General Polinomial Root Extractor that can works on any polinomial and the classic n-th Root algo that is capable to work (in general) just on Hypercube, is just a sub class of this General Polinomial Root Extractor.

Moreover, any Ring has the same properties shown here for Polinomials, will lead to similar zeros, or Roots. But this will require an Abstract Algebra discussion that is not what I would like to do here, since my purphose is to introduce young students to a new point of view or the known classic algebra.
solution of $\mathrm{x} 5-\mathrm{x}+1=0 . \mathrm{jpg}$

This is not a Numerical Solution, since it is an Algebraic Root Extractor, as the extraction of a known n-th Root is.

In both case, in fact, the Root will produce an Irrational Number require a truncation to print the Radical, or thet it was left under the Root Sign.

So I hope I've proved here that the concept of Radical and Root is much wider and lead to new interesting simple results can be presented without any abstract definition of Groups / Rings / Ideals etc...
